

Practical Concurrent and Parallel Programming VI

Performance and Scalability

Jørgen Staunstrup

- **Executors and Future (continued from Week 5)**
- Scalability, speed-up and loss (of scalability) classification
Example: QuickSort
- Lock striping
 - A case study with Hash maps

@Override

```
public void run() {  
    if ((high-low) < threshold) {  
        for (int i=low; i<=high; i++) if (isPrime(i)) lc.increment();  
    } else {  
        int mid= low+(high-low)/2;  
        pool.submit(new countPrimesTask(lc, low, mid, pool, threshold) );  
        pool.submit(new countPrimesTask(lc, mid+1, high, pool, threshold) );  
    }  
}
```

Shortcomings:

1. How to stop?
2. ~~Will create too many "small" tasks~~
3. Returning result (# primes)

Splitting tasks

```
public void run() {  
    if ((high-low) < threshold) {        ...  
    } else {  
        int mid= low+(high-low)/2;  
        Future<?> f1= pool.submit( new countPrimesTask(lc, low, mid,  
                                                         pool, threshold) );  
        Future<?> f2= pool.submit( new countPrimesTask(lc, mid+1, high,  
                                                         pool, threshold) );  
        ...  
    }  
}
```

Combining tasks

```
public void run() {
    if ((high-low) < threshold) {        ...
    } else {
        int mid= low+(high-low)/2;
        Future<?> f1= pool.submit( new countPrimesTask(lc, low, mid,
                                                    pool, threshold) );
        Future<?> f2= pool.submit( new countPrimesTask(lc, mid+1, high,
                                                    pool, threshold) );

        try {  f1.get();f2.get(); }
        catch (InterruptedException | ExecutionException e) {    }
    }
}
```

Does the order of f1.get and f2.get matter?

Combining tasks

```
public void run() {
    if ((high-low) < threshold) {        ...
    } else {
        int mid= low+(high-low)/2;
        Future<?> f1= pool.submit( new countPrimesTask(lc, low, mid,
                                                    pool, threshold) );
        Future<?> f2= pool.submit( new countPrimesTask(lc, mid+1, high,
                                                    pool, threshold) );

        try {  f1.get();f2.get(); }
        catch (InterruptedException | ExecutionException e) {    }
    }
}
```

Shortcomings:

- ~~1. How to stop?~~
- ~~2. Will create too many "small" tasks~~
3. Returning result (# primes)

How do we get the result
primes ?

- **Tasks** are a central concept for executors
- When designing a program using executors, first think about the tasks to be executed (e.g. [countPrimesTask](#))
 - Like for threads, tasks can be conveniently defined in their own class

```
public class countPrimesTask implements Runnable {
    private final int low;
    ...

    private static boolean isPrime(int n) {
        ...
    }

    public countPrimesTask(PrimeCounter lc, int low, int high,
        ExecutorService pool, int threshold) {
        this.lc      = lc;
        ...
    }

    @Override
    public void run() {
        ...
    }
}
```

- **Tasks** are a central concept for executors
- When designing a program using executors, first think about the tasks to be executed (e.g. [countPrimesTask](#))
 - Like for threads, tasks can be conveniently defined in their own class
- Ideally, tasks should be independent

Why?

countPrimesTask class

· 13

```
public class countPrimesTask implements Runnable {
    private final int low; private final int high; private final
    private final ExecutorService pool;
    private final PrimeCounter lc;

    private static boolean isPrime(int n) {...}
}

public countPrimesTask(PrimeCounter lc... ) {this.lc= lc;... }

@Override
public void run() {
    if ((high-low) < threshold) {
        for (int i=low; i<=high; i++) if (isPrime(i)) lc.increment();
    } else {
        int mid= low+(high-low)/2;
        Future<?> f1= pool.submit( new countPrimesTask(lc, ... ) );
        Future<?> f2= pool.submit( new countPrimesTask(lc, ... ) );
        try { f1.get();f2.get(); }
        catch (InterruptedException | ExecutionException e) { e.printStackTrace();
    }
}
}
```

Are countPrimesTasks
independent?

Code in countPrimesTask.java

```
class PrimeCounter {  
  
    private int count= 0;  
    public synchronized void increment() {  
        count= count + 1;  
    }  
    public synchronized int get() {  
        return count;  
    }  
    public synchronized void setZero() {  
        count= 0;  
    }  
}
```

PrimeCountExecutor class

· 16

- Kick-off class for the program
- It initializes the Executor service

```
class PrimeCountExecutor {  
    private ExecutorService pool;  
    ...  
    public PrimeCountExecutor () {  
        pool= new ForkJoinPool();  
        Future<?> done= pool.submit(new countPrimesTask( ... ));  
  
        try {    done.get();    }  
  
    }  
}
```

<https://docs.oracle.com/javase/tutorial/essential/concurrency/forkjoin.html>

Thread pools

· 17

```
class PrimeCountExecutor {  
    private ExecutorService pool;  
    ...  
    public PrimeCountExecutor () {  
        pool= new ForkJoinPool();  
        ...  
    }  
}
```

Thread pools

```
class PrimeCountExecutor {  
    private ExecutorService pool;  
    ...  
    public PrimeCountExecutor () {  
        pool= newFixedThreadPool(3);  
        ...  
    }  
}
```

<https://docs.oracle.com/javase/tutorial/essential/concurrency/pools.html>

Thread pools

· 19

```
class PrimeCountExecutor {  
    private ExecutorService pool;  
    ...  
    public PrimeCountExecutor () {  
        pool= newWorkStealingPool(x);  
        ...  
    }  
}
```

Quite a few more
types of ExecutorService

```
import java.util.concurrent.ForkJoinPool;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Future;
```

```
class PrimeCountExecutor {
    private ExecutorService pool;
    ...
    public PrimeCountExecutor () {
        pool= new ForkJoinPool( n );
        ...
    }
}
```

n specifies the number of CPUs that will be used

default value: [Runtime.availableProcessors\(\)](#)

<https://docs.oracle.com/javase/8/docs/api/java/util/concurrent/ForkJoinPool.html>

- Executors and Future
- **Scalability, speed-up and loss (of scalability) classification**
Example: QuickSort
- Lock striping
 - A case study with Hash maps

Quicksort

· 22

1 2 43 78 19 54 33 21 64 52 17 53

1 2 43 78 19 54 33 21 64 52 17 53

1 2 43 78 19 54 33 21 64 52 17 53

1 2 17 78 19 54 33 21 64 52 43 53

1 2 17 78 19 54 33 21 64 52 43 53

...

1 2 17 21 19 33 54 78 64 52 43 53

1 2 17 21 19 33 54 78 64 52 43 53

Two parts can be
sorted independently

Distributing work to threads

· 23

1 2 17 21 19 33 54 78 64 52 43 53

...

No further splitting when the sorting problem is smaller than a threshold (similarly to what we did for prime counting)

These tasks may differ in size !!

Quicksort executor (pseudo code)

· 24

```
class QuicksortTask implements Runnable {
    Task p; // low and high boundaries
    ExecutorService pool;

    @Override public void run() { qsort(p, pool, ... ); }

    public static void qsort(Task p, ExecutorService pool, ...
    ) {
        //split task in two: Low and High

        if (Low.size>= threshold) pool.submit( new
        QuicksortTask( pLow, pool, ... ))
            else Quicksort(pLow); //sequential sort

        if (High.size>= threshold) pool.submit( new
        QuicksortTask( pHigh, pool, ... ))
            else Quicksort(pHigh);

    }
}
```

Code in [QuickSortTask.java](#)

Termination (Quicksort)

· 28

How do we know when all task are done?

Termination

· 29

When can task a
finish?

`lowTask.get()` returns when `lowTask` has finished

`highTask.get()` returns when `highTask` has finished

```
@Override
public void run() { // modified Quicksort using Executor tasks
    ...

    //Waiting for longest running subtask to finish
    try {
        lowTask.get();
        highTask.get();
    } catch (InterruptedException | ExecutionException e) { e.printStackTrace(); }
}
```

```
@Override
public void run() { // modified Quicksort using Executor tasks
    int a= low;  int b= high;
    Future<?> lowTask= null;    Future<?> highTask= null;

    if (a < b) { ... // split array in two independent part

        if ((j-a)>= threshold)
            lowTask= pool.submit(new QuickSortTask(arr, a, j, pool, threshold));
        else // all remaining work done without starting more tasks
            SearchAndSort.qsort(arr, a, j);

        if ((b-i)>= threshold)
            highTask= pool.submit(new QuickSortTask(arr, i, b, pool, threshold));
        else // all remaining work done without starting more tasks
            SearchAndSort.qsort(arr, i, b);
    }

    //Waiting for longest running subtask to finish
    try {
        if (lowTask != null ) lowTaskF.get();
        if (highTask != null) highTaskF.get();
    } catch (InterruptedException | ExecutionException e) { e.printStackTrace(); }
}
```

We use Mark8Setup to measure runtime

```
private static void runSize(ExecutorService pool, int pSize, int threshold, int n) {
    final int[] intArray= fillIntArray(pSize);
    Benchmark.Mark8Setup("Quicksort Executor", String.format("%2d", n),
        new Benchmarkable() {

        public void setup() {
            shuffle(intArray);
        }

        public double applyAsDouble(int i) {
            Future<?> done= pool.submit(new QuickSortTask(intArray, 0, pSize-1, pool, threshold));
            PoolFinish(done);
            //testSorted(intArray); //only needed while testing
            return 0.0;
        }
    }
    );
}
```

Code in [PoolSortingBenchmarkable.java](#)

Sorting 100_000 numbers

- Starvation loss
 - Minimize the time that the task pool is empty
- Separation loss (best threshold)
 - Find a good threshold to distribute workload evenly
- Saturation loss (locking common data structure)
 - Minimize high thread contention in the problem
- Braking loss
 - Stop all tasks as soon as the problem is solved

QuickSort

Prime count

String search

Møller-Nielsen, P and Staunstrup, J, Problem-heap. A paradigm for multiprocessor algorithms. *Parallel Computing*, 4:63-74, 1987

Shut down

The `ExecutorService` can be shut down.

```
// Executor body  
...  
...  
  
pool.shutdown();
```

The challenge is often when to shut down

After shutdown the pool cannot be reused,
but you may assign it a new value (of type **`ExecutorService`**)

Both are used to specify the code of a task.

- Runnable cannot return a result
 - Overrides `run()`
- Callable returns a result (via a Future)
 - Overrides `call()`

Could Callables use shared data as well?

As illustrated by the Quicksort and countPrimes examples, Runnables may use shared data (e.g., to deliver a result)

Futures are an example of message passing (coming weeks)

Submit vs Execute

· 39

Both are used to spawn a task

- `pool.execute` does return a result
may complicate determining when to finish
- `pool.submit` returns a result (via a Future)

<https://docs.oracle.com/javase/8/docs/api/java/util/concurrent/Executor.html>

Callable example: dotProduct

· 40

Given two vectors x , y of equal size, their dot product equals

$$\sum_i x_i y_i$$

```
public class DotProductTask implements Callable<Integer> {  
    final int pos;  
    final int[] x, y;  
  
    public DotProductTask(int[] x, int[] y, int pos) {  
        this.x = x;  
        this.y = y;  
        this.pos = pos;  
    }  
  
    @Override  
    public Integer call() {  
        return x[pos] * y[pos];  
    }  
}
```

Each task is
doing a
multiplication

dotProduct – Future execution

· 41

Given two vectors x, y of equal size, their dot product equals $\sum_i x_i y_i$

```
...
List<DotProductTask> tasks = new ArrayList<DotProductTask>();

// Randomly initialize arrays x and y...

// Create the list of tasks (Futures) to execute
for (int i = 0; i < N; i++)
    tasks.add(new DotProductTask(x,y,i));

...

// Add all futures to the execution pool at once
List<Future<Integer>> futures = pool.invokeAll(tasks);
for(Future<Integer> f : futures) {
    result += f.get(); // Wait for each future to be executed
                    // and add partial result

pool.shutdown(); // We are sure to be done, so we shut down the pool
...
```

Code in [FuturesDotProduct.java](#)

What limits performance?

CPU-bound

- Eg. counting prime numbers, sorting,
- To speed up, add more CPUs (cores) (*exploitation*)

Input/output-bound

- Eg. I/O or reading from network
- To speed up, use more threads/tasks (*inherent*)

Synchronization-bound (Saturation loss)

- Eg. Algorithm using shared data structure
- **To speed up, improve shared data structure**
(*Rest of this lecture*)

- Executors and Future
- Scalability, speed-up and loss (of scalability) classification
Example: QuickSort
- **Lock striping**
 - **A case study with Hash maps**

Scalability of Java Collections

A *collection* is simply an object that groups multiple elements into a single unit

Package: `java.util`

Examples: `ArrayList`, `HashMap`, `TreeSet`, ...

<https://docs.oracle.com/javase/tutorial/collections/intro/index.html>

Methods: `add`, `remove`, `size`, `contains`, ...

Many of the classes have thread-safe/concurrent implementations

<https://www.baeldung.com/java-synchronized-collections>

Example: synchronizedCollection

· 45

```
import java.util.*;

public class syncCollectionExample {
    public static void main(String[] args) { new syncCollectionExample(); }

    public String getLast(ArrayList<String> l) {
        int last= l.size()-1;
        return l.get(last);
    }

    public static void delete(ArrayList<String> l) {
        int last= l.size()-1;
        l.remove(last);
    }

    public syncCollectionExample() {
        ArrayList<String> a= new ArrayList<String>(); // Collection
        a.add("A"); ...

        Collection<String> synColl = Collections.synchronizedCollection(a);
        ...
    }
}
```

Thread-safe
(but no locking !!!!)

Goetz p. 80

Example: synchronizedCollection

· 46

```
import java.util.*;

public class syncCollectionExample {
    public static void main(String[] args) { new syncCollectionExample(); }

    public String getLast(ArrayList<String> l) {
        int last= l.size()-1;
        return l.get(last);
    }

    public static void delete(ArrayList<String> l) {
        int last= l.size()-1;
        l.remove(last);
    }

    public syncCollectionExample() {
        ArrayList<String> a= new ArrayList<String>();
        a.add("A"); ...

        Collection<String> synColl = Collections.synchronizedCollection(a);
        ...
    }
}
```

Thread-safe?

Goetz p. 80

It is very important to note that for a program p :

p only accesses thread-safe classes

\Rightarrow

p is a thread-safe program

Making the synchronized ArrayList thread safe

```
import java.util.*;
public class syncCollectionExample {
    public static void main(String[] args) { new syncCollectionExample(); }

    public String getLast(ArrayList<String> l) {
        synchronized(l) {
            int last= l.size()-1;
            return l.get(last);
        }
    }

    public static void delete(ArrayList<String> l) {
        synchronized(l) {
            int last= l.size()-1;
            l.remove(last);
        }
    }

    public syncCollectionExample() {
        ...
    }
}
```

But then the advantage of the
synchronized collections is lost !!

Goetz p. 80

What if the data structure is huge?

and used by many threads?

for example:

a bank

Facebook updates

...

Would not work if everything is "synchronized"

What can we do?

Reduce locking !!

Example: A huge HashMap

Key value pairs: $\langle k1, v1 \rangle$, $\langle k2, v2 \rangle$, ...

```
class HashMap<K,V> {  
    ... // data structure  
    public V get(K k) { ... }  
    public V put(K k, V v) { ... }  
    public boolean containsKey(K k) { ... }  
    public int size() { return cachedSize; }  
    public V remove(K k) { ... }  
    ...  
}
```

Key	Value
Peter	20487612
Anna	51251218
Lena	34458318
Holger	89545010
Lisa	94959500

How to make it thread-safe?
(without making all the methods synchronized)

HashMap implementation

35

buckets

ItemNode

Example **get(10406)**

key k is 10406

k.hashCode() is 6

ItemNode

ItemNode

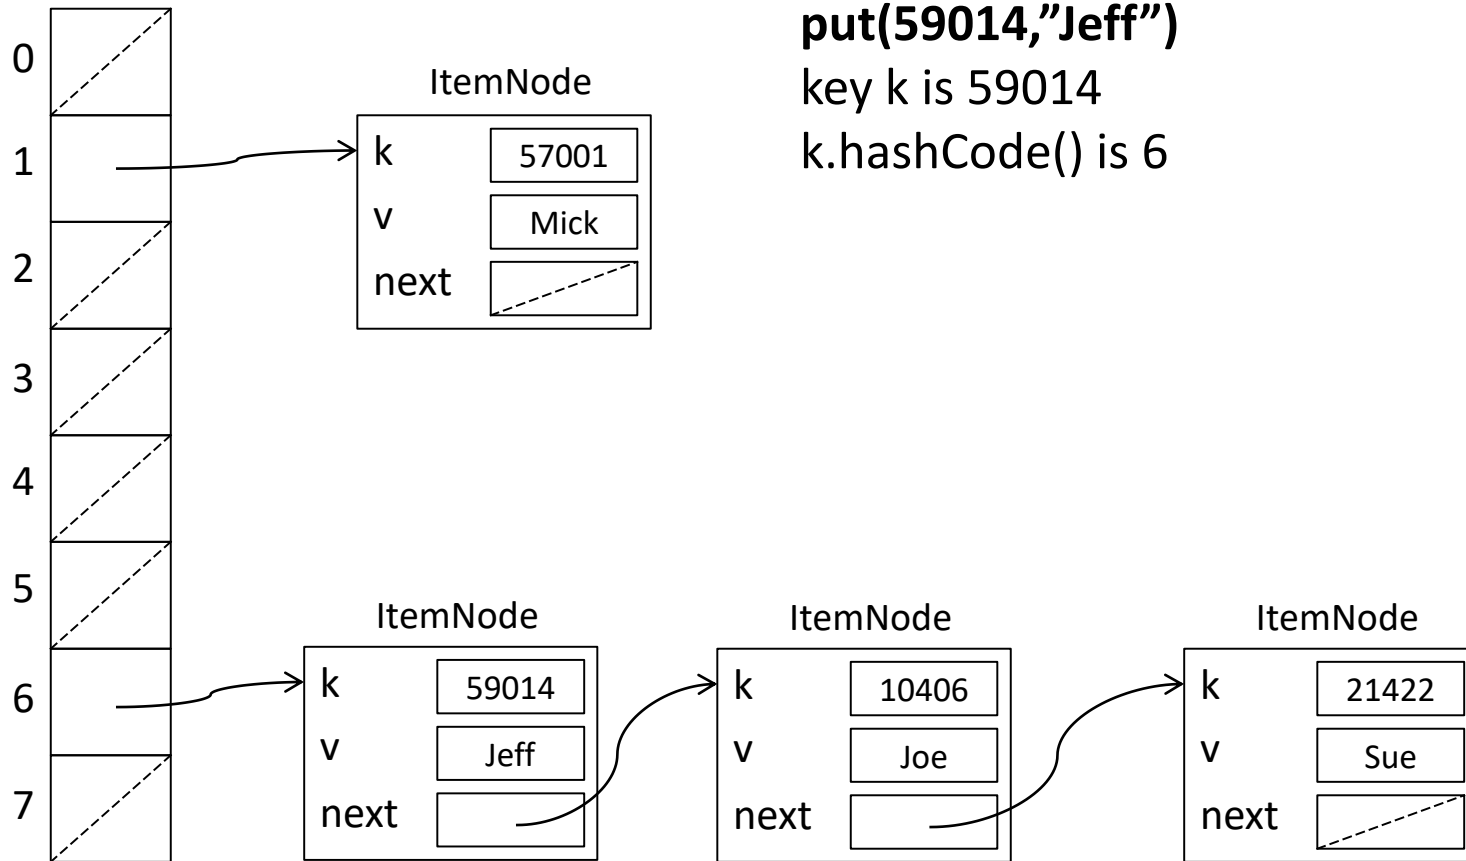

HaspMap put

· 54

buckets

Improving scalability – Lock striping

· 56

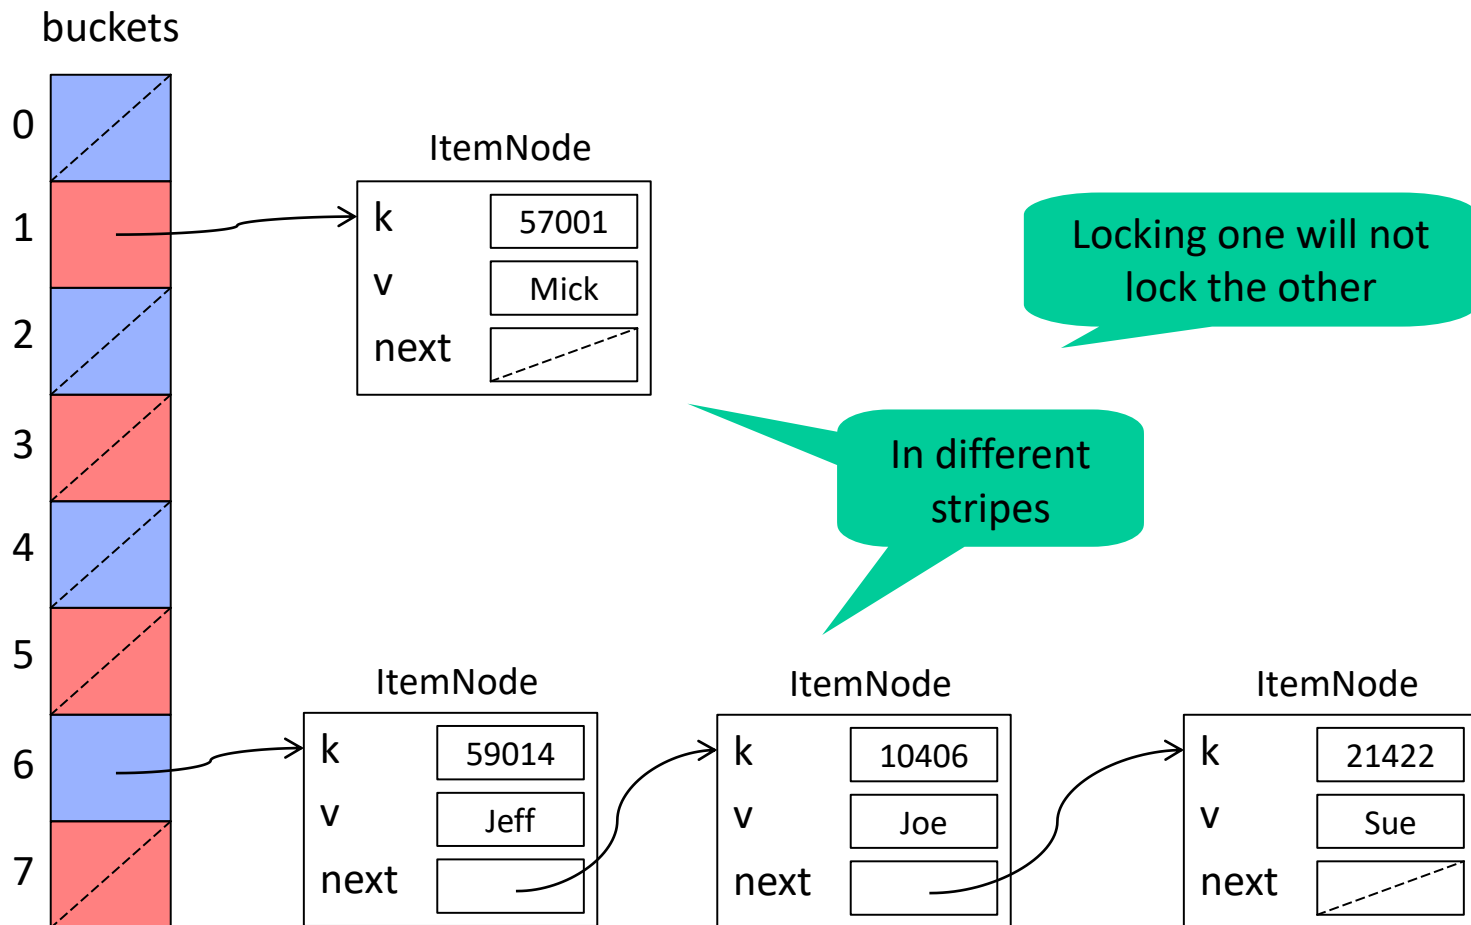

- Guarding the table with a single lock works
 - ... but does not scale well (actually **very** badly)
- Idea: Each bucket could have its own lock
- In practice
 - use fewer, to illustrate we use 4, locks
 - guard every 4th bucket with the same lock
 - locks[0] guards bucket 0, 4, 8, ... (stripe 0)
 - locks[1] guards bucket 1, 5, 9, ... (stripe 1) et
- With high probability
- two operations will work on different stripes
- hence will take different locks
- Less lock contention, better scalability

Bucket idea

· 57

Reducing locking

A web-shop, Facebook, ...

We must give up thread safety,

but still maintain some sort of consistency

Weeks 8 and 13
